N w Imidazopyridines as Serotonergic 5-HT<sub>3</sub> AntagonistsBACKGROUND OF THE INVENTION

The invention herein is directed to compounds and a method of treating gastrointestinal motility disorders of a mammal by administering to the mammal in need thereof a therapeutically effective amount of a compound disclosed herein or a pharmaceutically acceptable salt thereof. The method can be practiced to treat gastrointestinal motility disorders such as gastroesophageal reflux, diseases characterized by delayed gastric emptying, ileus, irritable bowel syndrome, and the like. The compounds of the invention are serotonergic 5-HT<sub>3</sub> antagonists and as such are useful for the treatment of conditions, for example, such as anxiety, psychoses and depression.

There are classes of compounds known for the treatment of such disorders. For example, azatetracycle compounds are disclosed in co-pending U.S. patent application serial no. 07/515,391 filed April 27, 1990, and N-Azabicyclo [3.3.0] octane amides of aromatic acids are disclosed in co-pending application serial no. 07/406,205 filed September 11, 1989.

Aza-adamantyl compounds are disclosed in U.S. Patent 4,816,453 and are mentioned generically in U.K. Patent 2,152,049A and Europ an application 0189002A2.

Azabicyclic nonanes are disclosed in European Patent application 0094742A2. Additional azabicyclic compounds are disclosed in U.S. Patents 4,797,387 and 4,797,406.

Benzamides have been known as 5-HT<sub>3</sub> antagonists and as compounds possessing gastrointestinal motility-enhancing properties. Benzamides of the following formula:

compounds wherein X can be an azabicycloalkane moiety and which exhibit gastrointestinal motility enhancing and/or 5-HT<sub>3</sub> antagonist properties are disclosed in EP 0094742A2 and in U.S. patent 4,797,406. The term "cycloalkyl" embraces cyclic radicals having three to about ten ring carbon atoms, preferably three to about six carbon atoms, such as cyclopropyl and cyclobutyl. The term "haloalkyl" embraces radicals wherein any one or more of the alkyl carbon atoms is substituted with one or more halo groups, preferably selected from bromo, chloro and fluoro. Specifically embraced by the term "haloalkyl" are monohaloalkyl, dihaloalkyl and polyhaloalkyl groups. A monohaloalkyl group, for example, may have either a bromo, a chloro, or a fluoro atom within the group. Dihalalkyl and polyhaloalkyl groups may be substituted with two or more of the same halo groups, or may have a combination of different halo groups. A dihaloalkyl group, for example, may have two bromo atoms, such as a dibromomethyl group, or two chloro atoms, such as a dichloromethyl group, or one bromo atom and one chloro atom, such as a bromochloromethyl group. Examples of a polyhaloalkyl are trifluoromethyl, 2,2,2-trifluoroethyl, perfluoroethyl and 2,2,3,3-tetrafluoropropyl groups. The terms "alkoxy" and "alkoxyalkyl" embrace linear or branched oxy-containing radicals each having alkyl portions of one to about ten carbon atoms, such as methoxy group.

Specific examples of alkyl groups are methyl, ethyl, n-propyl, isopropyl, n-butyl, sec-butyl, iso-butyl, tert-butyl, n-pentyl, iso-pentyl, methyl-butyl, dimethylbutyl and neopentyl. Typical alkenyl and alkynyl groups may have one

unsaturated bond, such as an allyl group, or may have a plurality or unsaturated bonds, with such plurality of bonds either adjacent, such as allene-type structures, or in conjugation, or separated by several saturated carbons.

Included within the family of compounds of the described are the tautomeric forms of the described compounds, isomeric forms including diastereoisomers and individual enantiomers, and the pharmaceutically-acceptable salts thereof. The term "pharmaceutically-acceptable salts" embraces salts commonly used to form alkali metal salts and to form addition salts of free acids or free bases. Since the compounds contain basic nitrogen atoms, such salts are typically acid addition salts. The phrase "pharmaceutically-acceptable salts" is intended to embrace alkyl quaternary ammonium salts and n-oxides. The nature of the salt is not critical, provided that it is pharmaceutically acceptable, and acids which may be employed to form such salts are, of course, well known to those skilled in this art. Examples of acids which may be employed to form pharmaceutically acceptable acid addition salts include such inorganic acids as hydrochloric acid, sulfuric acid and phosphoric acid, and such organic acids as maleic acid, succinic acid and citric acid. Other pharmaceutically acceptable salts include salts with alkali metals or alkaline earth metals, such as sodium, potassium, calcium and magnesium, or with organic bases, such as dicyclohexylamine.

All of these salts may be prepared by conventional means by reacting, for example, the appropriate acid or base with the corresponding compound of the invention.

The compounds that are the subject of the invention herein can be prepared according to the following reaction schemes.

#### SCHEME 1

The preparation of compounds of formula I wherein the Ar group is A is shown in Scheme I. Compounds of formula IA are prepared starting from commercially available 2-aminonicotinic acid 1. Chloroacetaldehyde is reacted with 1 at elevated temperature in an alcoholic solvent (preferably EtOH at reflux) to afford compound 2A, which is converted to the acid chloride by conventional methods (preferably thionyl chloride/chloroform/dimethylformamide at reflux). This acid chloride 2B is then reacted with the appropriate amine 3 in the presence of a tertiary amine (preferably triethylamine) in a polar organic solvent (preferably dimethylformamide) to afford the desired compounds of formula IA. Alternatively, the imidazopyridine carboxylic acid 2A is reacted with the amine 3 using other acid-activating reagents (dicyclohexylcarbodiimide, iso-butylchloroformate, carbonyldiimidazole (CDI), etc.; preferably CDI in dimethylformamide at room temperature) to afford compounds of formula IA.

Ring halogenated analogs of formula IA' are prepared according to scheme I. 2-Aminonicotinic acid 1 is converted to its methyl ester by conventional means. Treatment of this ester with halogenating reagents (NBS, NCS, Cl<sub>2</sub>, t-butylhypochlorite; preferably t-butylhypochlorite/methanol/room temperature) gives rise to the ring halogenated intermediate 4, which is converted to the imidazopyridine carboxylic acid ester 5A using conditions described above for the preparation of 2A. The corresponding imidazopyridine carboxylic acid 5B is converted to compounds of formula IA' using reagents and conditions described above for the preparation of IA from 2A.

#### SCHEME 2

The preparation of compounds of formulae IB, IC, ID, and IE are shown in scheme 2. In each case, the known acids 10 [EP 0254584A2, J. Medicinal Chemistry (1990), 33, 1924], 11 [EP 0289170A2, J. Medicinal Chemistry (1990), 33, 1924], 12 & 13 [EP 0289170A2, J. Medicinal Chemistry (1990), 33, 1929] are reacted with the appropriate amine or alcohol under conditions analogous to those described for scheme 1 or as described in EP 0254584A2 and EP 0289170A2.

## SCHEME 3

The preparation of compounds of formula IF are shown in scheme 3. 2-Aminopyridine 14 is reacted with ethyl bromopyruvate 15 in an alcoholic solvent (preferably ethanol) to afford the imidazopyridine carboxylic acid ester 16A. Hydrolysis of the ester to the acid 16B occurs under conventional acid-catalyzed conditions. Conversion of 16B to amides and ester of formula IF is affected by employing one of a number of acid-activating reagents as cited above [preferably carbonyldiimidazole (CDI) in dimethylformamide at room temperature].

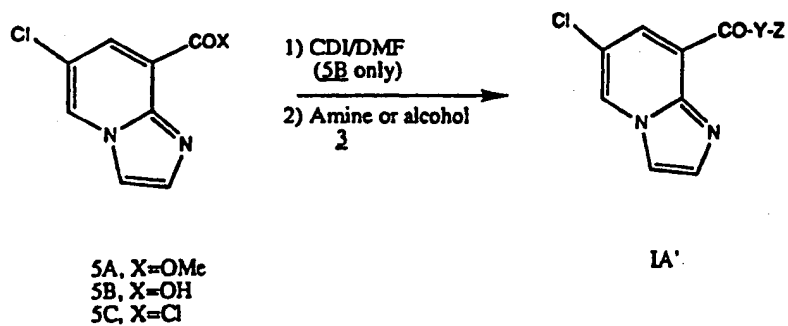

## SCHEME 4

The preparation of compounds of formulae I-G and I-H are shown in Scheme 4. The known triazole aldehyde 17 [G. Jones et al., J. Chemical Society Perkin I (1981), 78] is oxidized by use of chromium trioxide/sulfuric acid or other conventional oxidizing agents to afford the triazole carboxylic acid 18. Coupling of 18 with the appropriate amine or alcohol 3 using conditions cited above [preferably CDI in dimethylformamide at room temperature] affords the desired triazoles of formula 1-G.

For preparation of compounds of formula I-H, the known lithiated compound 19 [B. Abarca et al, J. Chemical Society Perkin I (1985), 1897] is quenched with carbon dioxide or alkylhaloformate to afford 20B and 20A, respectively. 20A is converted to the acid 20B by conventional acid-catalyzed hydrolysis. Coupling of 20B with the appropriate amine or alcohol 3 is affected by using the conditions sited above [preferably CDI in dimethylformamide at room temperature] to afford the desired I-H. Alternatively, the appropriate amine 3 is converted to its carbamoyl halide 21 (Q = Cl, Br) or isocyanate 22. The lithiated species 19 is directly quenched with 21 or 22 to directly afford I-H (Y = NH).

These examples, as well as all examples herein, are given by way of illustration only and are not to be construed as limiting the invention, either in spirit or scope, as many modifications, both in materials and methods, will be apparent from this disclosure to those skilled in the art. In these examples, temperatures are given in degrees Celsius (°C) and quantities of materials in grams and milliliters unless otherwise noted.

Procedure

The compound of example C (1.1 g, 0.0047 mol) was suspended in  $\text{CHCl}_3$ /DMF (25 ml/3 drops).  $\text{SOCl}_2$  (560 mg/0.338 ml, 0.0047 mol) was added and the mixture was heated to reflux with additional  $\text{SOCl}_2$  added until tlc (5% EtOH/ $\text{CH}_2\text{Cl}_2$ /1/10%  $\text{NH}_4\text{OH}$ ) indicated that the starting material was consumed. The mixture was concentrated in vacuo, azeotroping once with toluene.

To the residue, dissolved in DMF (15 ml) and cooled in an ice bath, was added  $\text{Et}_3\text{N}$  (1.19 g/1.64 ml, 0.0118 mol) followed by endo-4-amino-1-azabicyclo[3.3.1]nonane (649 mg, 0.0047 mol) dissolved in 5 ml of DMF. The compounds herein exhibit 5-HT<sub>3</sub> antagonism. 5-HT<sub>3</sub> antagonism can be determined by the radioligand receptor binding assay as described herein and in the in vivo Bezold-Jarisch reflex procedure.

Serotonin (5-HT<sub>3</sub>)Procedure:

GR65630 binds to the 5-HT<sub>3</sub> receptor. Brain cortices are obtained from male rats and a membrane fraction prepared by standard techniques. 0.04 mg of membrane prep is incubated with 0.2 nM [<sup>3</sup>H]-GR65630 for 60 minutes at 22°C. Non-specific binding is estimated in the presence of 1 uM ICS 205-930. Membranes are filtered and washed 3 times and the filters are counted to determine [<sup>3</sup>H]-GR65630 specifically bound.\*

The test sample is administered i.p. (mg/kg) to a group of 3 mice. Thirty minutes later, a 5-HT (0.25 mg/kg i.v.)-induced bradycardia is recorded in pentobarbital anesthetized animals. A greater than 50 percent (>50) reduction in the bradycardic response relative to vehicle-treated control mice is considered significant.
